1.264 Lecture 6

Data modeling

1. Data models

- Data model is representation of
 - Things (or entities or objects) of importance to a business
 - How the things relate to each other
- It is built and modified until it represents the business well enough to write a system.
- Data models are extended to become class diagrams in the Unified Modeling Language [UML] by adding the behaviors of each entity to the model
- Data models are sometimes built during requirements, and other times during design phase
 - The earlier the better. I always build them during requirements.

Logical data modeling

- Method to discover the data, relationships and rules of a business, collectively called the business rules
- Logical data models are the basis of:
 - Physical data models, or actual databases
 - Applications, parts of which can be automatically generated from the data model

Small model for broker of transportation services

- Small, but says a lot about broker
- Gives good picture of what database should look like
- Also gives good picture of underlying business rules of broker
 - Useful in requirements analysis and scrubbing!

Transportation Broker Data Model

Broker Business Rules

- A carrier can be associated with many offices
- An office can be associated with many carriers
- A carrier can issue many contracts
- A contract is issued by one carrier
- An office can employ many agents
- An agent is employed by one office
- An agent can sell many contracts
- A contract is serviced by only one agent
- A contract can serve to carry only one commodity type
- A commodity type can be carried under many contracts
- A contract can be associated with many equipment types
- An equipment type can be associated with many contracts
- A customer can be served by many contracts
- A contract covers one customer

Data model purpose

- Business needs to build logical data model so users and developers both understand business rules of company
 - Models enable users and developers to have single view of system
 - Sometimes users note this is first time they understood business rules!
- Converting logical to physical data model (database) is very straightforward these days.
 - Little need for separate physical model for online databases
 - Create integer system-generated keys instead of strings and composite keys for performance
 - We still create separate physical models for data warehouses, read-only databases and some other special cases

2. Data modeling concepts

- Entities (objects, tables)
- Attributes (properties)
- Keys (primary and foreign)
- Relationships
- Referential integrity

Entity type and entity occurrence

Entity type

Entity occurrence

Department

DeptNbr DeptName DeptType DeptStatus

Department													
DeptNbr	DeptName	DeptType	DeptStatus										
930	Receiving	Mfg	Active										
378	Assembly	Mfg	Active										
372	Finance	Adm	Active										
923	Planning	Adm	Active										
483	Construction	Plant	Inactive										

Entities

- "Department" is an entity type
 - In a software program, "department" is a class
- "Department 101" is an occurrence of entity type "Department"
 - In a software program, "department 101" is an object, which is an instance of class "department"
- Entities are things, often physical, that have facts associated with them.
- Processes are almost never entities. For example:
 - Order entry is not an entity
 - Orders and customers are entities
 - Reports are not entities
- Entity type descriptions should be as extensive as possible in developing a model.

Entity type description

- Poor description (I've seen lots of these)
 - Vendor: Someone we buy products from.
- Good description (I've never seen one like this in real life!)
 - Vendor: A US corporation we have reviewed with respect to their qualifications for providing products to our company. Vendors are rated based on price, quality, delivery performance and financial stability. Each vendor is classified by one vendor status: approval pending, approved, rejected or inactive. This approval decision is made in a weekly meeting among purchasing, manufacturing and finance. Purchasing requests that rejected vendors be kept in the database for future reference. Purchasing expects 500 vendors will be maintained at any one time. Of these, 200 will be active, 25 pending, 75 inactive and 100 rejected. Contact Joan Smith in Purchasing for more information.

Attributes

- Attributes are a data item or property associated with an entity type
 - They are typically nouns (quantity, type, color, ...)
 - Example: Employee
 - ID
 - Name
 - Social security number
 - Address
 - Phone

Entity type/attribute exercise

1. Identify which are types and which are attributes:

- Instructor
- Student
- Course section number
- Building name
- Course number
- Textbook price
- Teaching asst (TA) name
- Instructor ID
- Textbook author
- Course title
- Textbook
- Classroom
- Textbook ISBN
- Section days

- Office hours
- Textbook title
- Classroom number
- TA student ID
- Instructor name
- Textbook publisher
- Section capacity
- Course objective
- Copyright date
- Building number
- Course section
- Course
- Building
- Section time
- Classroom capacity

Entity type/attribute exercise

2. Draw an entity type box and its attributes for each:

- Instructor
- Student
- Course section number
- Building name
- Course number
- Textbook price
- Teaching asst (TA) name
- Instructor ID
- Textbook author
- Course title
- Textbook
- Classroom
- Textbook ISBN
- Section days

- Office hours
- Textbook title
- Classroom number
- TA student ID
- Instructor name
- Textbook publisher
- Section capacity
- Course objective
- Copyright date
- Building number
- Course section
- Course
- Building
- Section time
- Classroom capacity

Solution

Domain entity type

- Also called pick list, validation list, etc.
- Department name example

Domain entity type

Department													
DeptNbr	DeptName	DeptType	DeptStatus										
930	Receiving	Mfg	Active										
378	Assembly	Mfg	Active										
372	Finance	Adm	Active										
923	Planning	Adm	Active										
483	Construction	Plant	Inactive										

ValidDeptType
DeptType
Mfg
Adm
Plant
Sales
Operations

Relationships

- Entities are drawn as boxes, as in the broker diagram
- Relationships are lines between boxes
- Cardinality is the expected number of related occurrences between the two entities in the relationship

(Instructor)

Relationships + cardinality = business rules

(Course section)

Relationships and Cardinality

Exercise: Draw the relationships among these entities

Relationships and Cardinality

We're getting there: we've defined entities, attributes and relationships. We still have to add keys and more entities

Course example

- Course may be offered in many (0,1 or more) sections
- Course section must be associated with a course
- Course section may be taught by many (0,1 or more) TAs
- TA may teach many (0, 1 or more) course sections
- Course section must be taught by 1 instructor (??)
- Instructor may teach many sections

- Course may use many textbooks (all sections use same)
- Textbook may be used in many courses
- Building may contain many rooms
- A room is in only one building
- A course section may use a room
- A room may be used by many course sections (not at same time)

Keys

- Primary key: one or more attributes that uniquely identify a record.
 - What would you use in a customer database of 100,000 people and no unique customer id?
 - Name not unique
 - Add birthdate, but not guaranteed to be unique
 - Address can change
 - Can use social security number, but not everyone has one
 - Privacy is an issue
 - Issues in choosing a primary key
 - Stability
 - Control
 - Use a system generated key if possible in many cases

Foreign keys

 Primary key of the <u>independent</u> or parent entity type is maintained as a non-key attribute in the <u>dependent</u> or child entity type

						· ·			• •															-									• •					
						+ ·			+ •		/ ·	+							+			+		-		+		V.		+				-			÷	
				-								-									-							- \										
									- 1																													
-		-	 -	-	1	_	_					1	-					-				-		-				-	- 🔪	1								
		-					Em	plo	yee	е														-														
			 -		Γ.	F	- 10					-						-	+			+				+		_					<u> </u>	- +			÷ -	
					1	Em	עופ																				(De	epa	artı	me	ent	7					
					ŧ	‡Dep	arti	me	ntD	еp	t/D	P	×O	- ·	 	-	~	 		 _	÷	÷.,	-	1	_	- 1-	-	Ð	enf	HD								
	-	-	 -			E main	- Ein	eth I	lom	-			-	-				-	-					-		1												-
						Emt	JEIN	SUV	am	e										 								De	ept	Nε	am	е						
						Emp	oLa:	stΝ	am	е		ŀ							+			+				+			÷.,					-			÷ -	
		-	 -		L							J						-										_					Ζ.					
					1).								 																		
																			-																			
						÷ ·			÷ ·			+							+	 						+				+								

Flip these: Dept on left, emp on right for consistency With next slides

Foreign keys

Database requires a valid department number when employee is added Employee ID is the unique identifier of employees; department number is not needed as part of the employee primary key

Bob

5325

Identifying foreign keys

Independent/parent

Dependent/child (must contain, as a foreign key, the primary key of the independent entity)

To keep it simple, assume this is a charter airline, and every flight has a different number

Identifying foreign keys

Flight														
FlightNbr FlightDate DepartTime ArrivalTime														
243	9/24/00	9:00am	11:00am											
253	9/24/00	10:00am	12:30pm											
52	9/24/00	11:00am	2:00pm											

FlightSeat													
FlightNbr	SeatNbr	SeatStatus	SeatDescription										
243	8A	Confirmed	Window										
243	7D	Reserved	Aisle										
243	14E	Open	Center										
253	1F	Open	Window										
253	43A	Confirmed	Window										

Flight number must be part of the flight seat primary key; this is different than employee and department, where department is not required.

(Also, this schema violates normalization, the next topic. Can you see the problem?)

Foreign keys (many-many relationships)

Primary key of parent is used in primary key of child

Independent

Dependent

Independent

Vehicle can be driven by many drivers; driver can drive many vehicles

Many-to-many relationships with foreign keys

	Vehicle		Vehicle	Driver	Driver								
VehicleID	VehicleMake	VehicleModel	VehicleID	DriverID	DriverID	DriverName	DriverLicenseNbr						
35	Volvo	Wagon	35	900	253	Ken	A23423						
33	Ford	Sedan	35	253	900	Jen	B89987						
89	GMC	Truck	89	900									

Never create an entity with vehicle1, vehicle2,... !

Referential integrity

- Referential integrity maintains the validity of foreign keys when the primary key in the parent table changes. (The database software does this.)
 - Every foreign key either matches a primary key or is null
- Cascade rules. Choose among two delete options:
 - Cascade restrict: Rows in the primary key table can't be deleted unless all corresponding rows in the foreign key tables have been deleted.
 - E.g., when deleting a department, don't delete all the employees
 - Cascade delete: When rows in the primary key table are deleted, associated rows in foreign key tables are also deleted
 - E.g. When deleting an order, delete all items in the order
 - Cascade update: When rows (keys) in the primary key table are updated, associated rows in foreign key tables are also updated
 - E.g., when changing a department number, change the employee department numbers

Recursive relation

 We'll cover this in more detail under SQL. Pretend the recursive relation is between two tables, the real one and a virtual copy. In this case, a manager table and an employee table. Proceed as usual, with a small syntax change.

Sets of recursive relations

Steering column makes up part of steering system Steering column is made up of shafts, linkages, etc.

Variant (category) relations

Time dependent relation
